Cross-over wanted

SCHROEDER FREQUENCY REVISITED

About the presentation

- What is the significant properties of the two frequency regions?
  - Low frequency region – Modal Region
  - High frequency region – Schroeder Region
- Why care?
- Common misunderstandings
- The Schroeder Frequency
- Suggesting a revised cross-over region
- Handling the non-diffuse cases

The two frequency regions

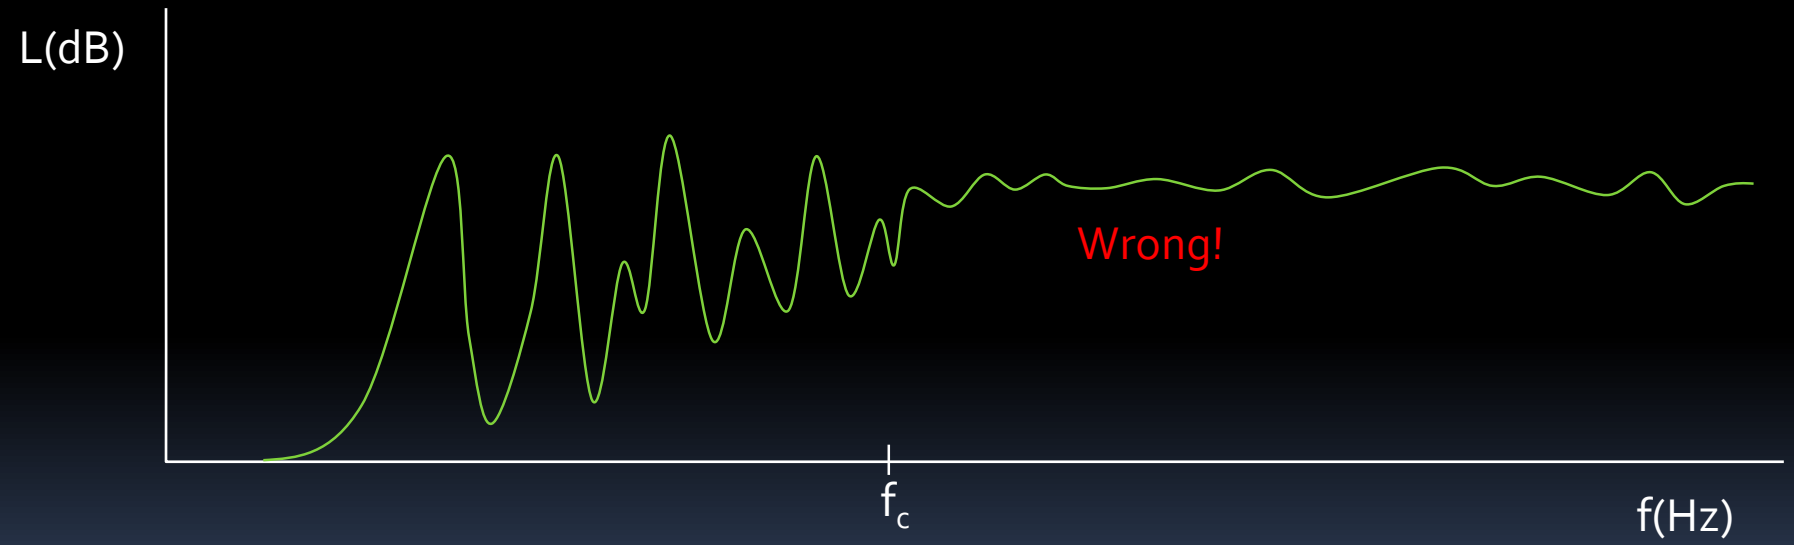
- Low frequency region – Modal Region
  - Dominated by separate modes, but clusters of overlapping modes may occur
  - Lowest mode in room of length L $f = 170/L$
  - Half-power mode bandwidth $B = 2.2/T$
  - Average mode spacing $\Delta f = \frac{c^3}{4\pi V f^2}$
- High frequency region – Schroeder Region
  - Dominated by stochastic level outcome from overlapping modes
  - Best described by statistical properties
  - Average spacing between maxima $\Delta F_{avr} = 4/T$
  - Average peak-to-dip level difference $\Delta L_{avr} \sim 10dB$

Why care?

- In the high frequency region, energy-based prediction methods can work well, sound is well described as particles or rays
- In the Modal Region, single modes dominates

Common misunderstanding

- Smooth frequency response in the HF region



The Schroeder Frequency

- A room of volume V and reverberation time T
- The low limit of the high frequency region

$$f_c = 2000\sqrt{\frac{T}{V}}$$

corresponding to 3-fold modal overlap

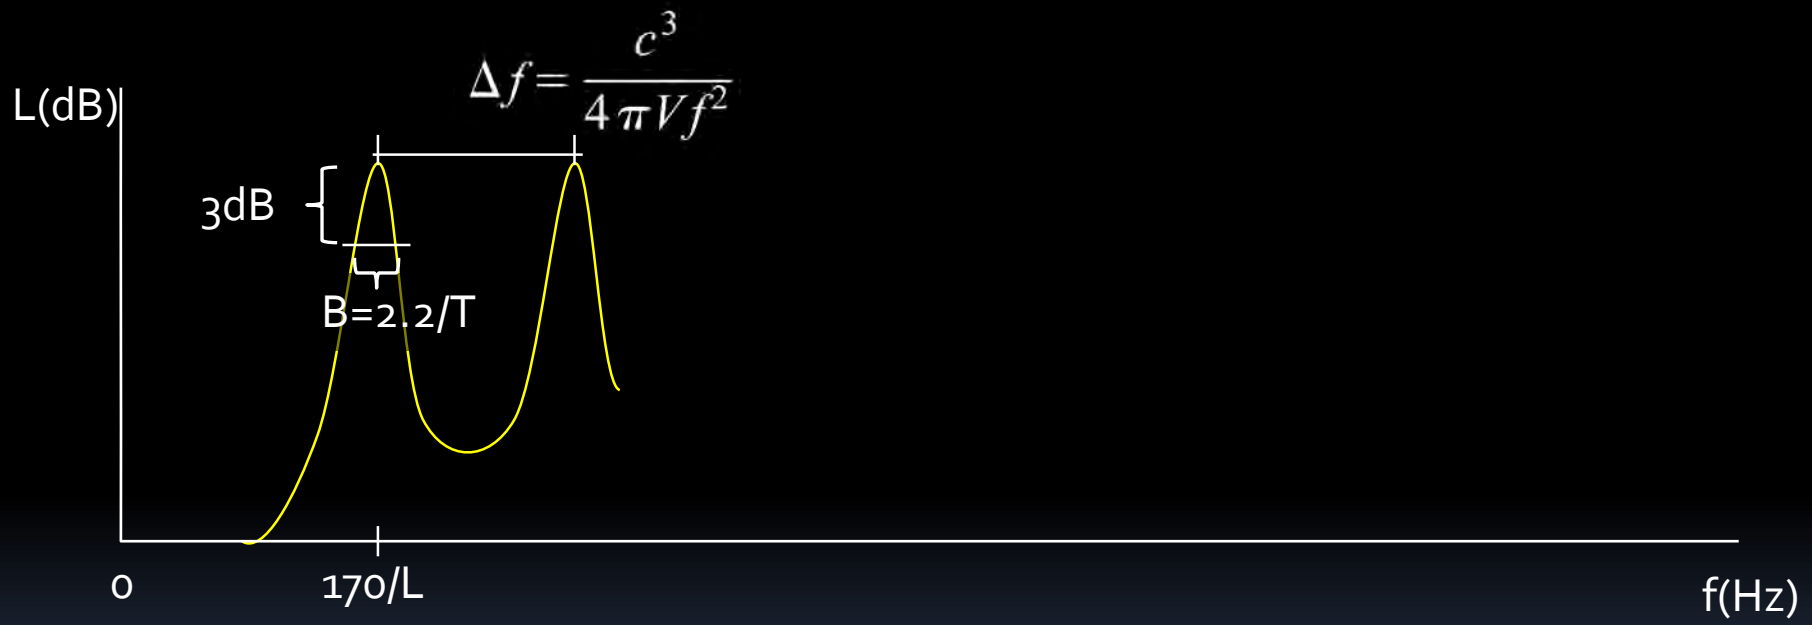
- Originally, Schroeder, Kuttruf and Thiele suggested 10-fold overlap and the factor 4000, but after collecting more data, Schroeder in 1962 recommended the limit as expressed above

Validity of f_c

- High frequency properties can be expected above f_c , according to Schroeders' intention
- However, it is not established that the same properties can NOT be found below f_c
- f_c was not designed to determine the upper limit of the Modal Region
- Further discussion of the cross-over region follows

Modal Region

Frequency Response (Transfer Function)



Introducing Schroeder Region

What cross-over?

- Either the cross-over is a single frequency limit or a frequency region, we require:
- It should be measurable!
- In particular, since $0.45 \cdot f_c$ has an average peak spacing, 4/T, characteristic for the high frequency region, we require either:
  - Average level fluctuation around $0.45 \cdot f_c$ must differ from those of the high frequency region (This can be decided by further measurements)
  - Or, $0.45 \cdot f_c$ must be the lower limit of the Schroeder Region

Conclusions & Further Work

- A measurable cross-over between the Modal Region and the Schroeder Region remains to settle
- In further work, the transition between $0.45 \cdot f_c$ and f_c will be investigated
- Cases of prominent modes in the Schroeder Region should not be used as argument for further extension of the cross-over region
- Instead, one should question whether the conditions for f_c are fulfilled
- For example, an effective absorbing ceiling may create a 2-D horizontal field. The lower modal density would imply less modal overlap, thus high frequency properties can not be expected
- Complex harmonic modes (pitch) may be perceived above f_c

Annex: $f_{c,2D} = 25000 \cdot T/S$

- 2-D sound field (tangential,horizontal, x-y) in cuboid with floor area S=XY and a sound-absorbing ceiling; Number of modes derived from eigenmode-space, $N=\pi S(f/c)^2$, shall increase by 3 in a frequency interval equal to the modal bandwidth $B=\ln 10^6/(2\pi T)$, which occurs at the limit frequency

  $f_c = 3c^2 \cdot T/(S \cdot \ln 10^6) \sim 25000 \cdot T/S$

  inserting Sabine's $T=\ln 10^6 \cdot 4V/(cA)$, where $V=S \cdot H$, H room heigth, and A the absorption area, the critical wavelength becomes

  $\lambda_c = A/(12H)$

Thank you
